
Worst-Case Execution Time Analysis

Prof. Dr. Jian-Jia Chen

LS 12, TU Dortmund

28, Nov., 2018

Most Essential Assumptions for Real-Time Systems

Upper bound on the execution times:

- Commonly, called the *Worst-Case Execution Time(WCET)*

What does Execution Time Depend on

- Input parameters
 - Algorithm parameters
 - Problem size
 - etc.
- Initial states and intermediate states of the system for executing
 - Cache configuration, replacement policies
 - Pipelines
 - Speculations
 - etc.
- Interferences from the environment
 - Scheduling
 - Interrupts
 - etc.

How to Derive the Worst-Case Execution Time (WCET)

- Most of industry's best practice
 - Measure it: determine WCET directly by running or simulating a set of inputs.
 - There is no guarantee to give an upper bound of the WCET.
 - The derived WCET could be too optimistic.
 - Exhaustive execution: by considering the set of all the possible inputs
 - In general, not possible
 - The inputs have to cover all the possible initial states and intermediate states of the system, which is also usually not possible.
- Compute it
 - In general, not possible neither, as computing (tight) WCET for a program is *uncomputable* by Turing machines.
 - Based on some structures, it is possible and the derived solution is a safe upper bound of the WCET.

Why is It Uncomputable?

Halting Problem

Given the description of a Turing machine m and its input x , the problem is to answer whether the machine halts on x .

Theorem

Halting Problem is undecidable (uncomputable). In other words, one cannot use an algorithm to decide whether another algorithm m halts on a specific input.

WCET is undecidable

It is even undecidable if it terminates at all. Deriving the WCET is of course of undecidable.

Please refer to the textbook of Computational Complexity by Prof. Papadimitriou.

Execution Time Distribution

Our objectives:

- *Upper bound* of execution time as tightly as possible.
- All control-flow paths, by considering all possible inputs.
- All paths through the architecture, resulting from the potential initial and assumed intermediate architectural states.

Timing Analysis

By considering systems, in general, with

- finite architectural configurations, finite input domains, and bounded loops and recursion,

WCET is computable.

Timing Analysis

By considering systems, in general, with

- finite architectural configurations, finite input domains, and bounded loops and recursion,

WCET is computable.

But....., the search space is too large to explore it exhaustively!

Why is It Hard for Analyzing WCET?

Execution time $e(i)$ of machine instruction i

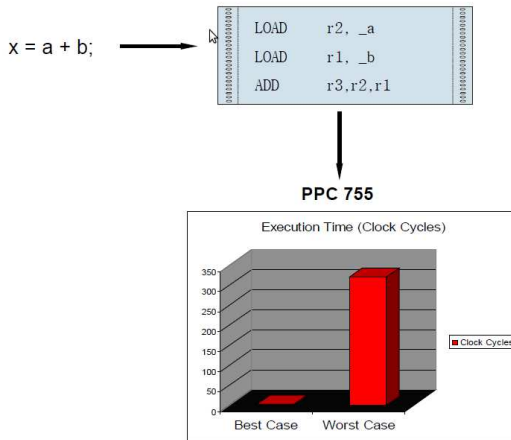

- In the good old time:
 $e(i)$ is a constant c , which could be found in the data sheet
- Nowadays, especially for high-performance processors:
 $e(i)$ also depends on the (architectural) execution state s .

$$\min\{e(i, s) | s \in S\} \leq e(i) \leq \max\{e(i, s) | s \in S\},$$

where S is the set of all states.

- Using $\max\{e(i, s) | s \in S\}$ is safe for WCET, but might be not tight since some states in S might not be possible reached by some inputs.
- Execution history, resulting in a smaller set of reachable execution states, has to be enforced to improve the tightness of the analysis.

Variability of Execution Times

Wilhelm et al.

Timing Accidents and Penalties

- Timing Accident: cause for an increase of the execution time of an instruction
- Timing Penalty: the associated increase
- Types of timing accidents
 - Cache misses
 - Pipeline stalls
 - Branch mispredictions
 - Bus collisions
 - Memory refresh of DRAM
 - TLB miss

Overall Approach: Modularization

- Architecture Analysis:
 - Use Abstract Interpretation.
 - Exclude as many Timing Accidents as possible during analysis.
 - Certain timing accidents will never happen, e.g., at a certain program point, instruction fetch will never cause a cache miss.
 - The more accidents excluded, the lower (better) the upper bound.
 - Determine WCET for basic blocks, based on context information.
- Worst-Case Path Determination:
 - Map control flow graph to an Integer Linear Program (ILP).
 - Determine upper bound and associated path.

High-Level Objectives: Upper Bound of WCET

- It must be safe, i.e., not underestimate.
- It should be tight, i.e., not far away from real WCET.
- The analysis effort must be tolerable.

Overall Structure

Introduction

Program Path Analysis

Static Analysis

Value Analysis

Cache Analysis

Control Flow Graph (CFG)

```
what_is_this {  
1   read (a,b);  
2   done = FALSE;  
3   repeat {  
4     if (a>b)  
5       a = a-b;  
6     elseif (b>a)  
7       b = b-a;  
8     else done = TRUE;  
9   } until done;  
10  write (a);  
}
```

Basic Blocks

Definition: *A basic block is a sequence of instructions where the control flow enters at the beginning and exits at the end, in which it is highly amenable to analysis.*

$a[0] := b[0] + c[0]$

$a[1] := b[3] + c[3]$

$a[2] := b[6] + c[6]$

$d := a[0] * a[1]$

$e := d / a[2]$

if $e < 10$ goto L

Basic Blocks

Definition: *A basic block is a sequence of instructions where the control flow enters at the beginning and exits at the end, in which it is highly amenable to analysis.*

Determining the basic blocks

- Beginning:
 - the first instruction
 - targets of un/conditional jumps
 - instructions that follow un/conditional jumps

$a[0] := b[0] + c[0]$

$a[1] := b[3] + c[3]$

$a[2] := b[6] + c[6]$

$d := a[0] * a[1]$

$e := d / a[2]$

if $e < 10$ goto L

- Ending:
 - the basic block consists of the block beginning and runs until the next block beginning (exclusive) or until the program ends

Program Path Analysis

- Problem: Which sequence of instructions is executed in the worst case (i.e., the longest execution time)?
- Input:
 - Timing information for each basic block, derived from static analysis (value/cache/pipeline analysis)
 - Loop bounds by specification
 - CFG derived from the executable binary program
- Basic Concept:
 - Transform structure of CFG into a set of (integer) linear equations
 - Solution of the Integer Linear Program (ILP) yields bound on the WCET.

Program Path Analysis: Formal Definition

Input

A CFG with N basic blocks, in which each basic block B_i has a worst-case execution time c_i , given by static analysis.

Output

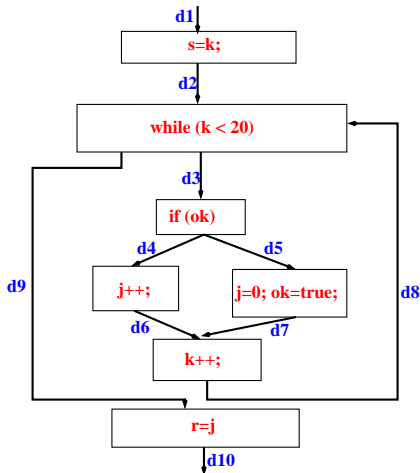

Suppose that each block B_i is executed *exactly* x_i times. What is the worst-case execution time

$$WCET = \sum_{i=1}^N c_i \cdot x_i,$$

such that the values of x_i s satisfy the structural constraints in the CFG?

Note that additional constraints provided by the programmer (bounds for loop counters, etc.) can also be included.

Example for CFG Constraints

Flow equations: (x_i is a variable)

$$d_1 = d_2 = x_1$$

$$d_3 + d_9 = d_2 + d_8 = x_2$$

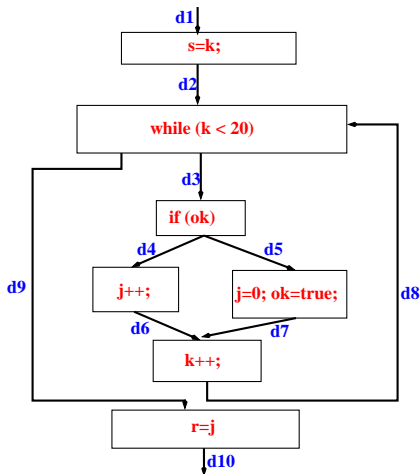

$$d_4 + d_5 = d_3 = x_3$$

$$d_6 + d_7 = d_8 = x_4$$

$$d_4 = d_6 = x_5$$

$$d_5 = d_7 = x_6$$

Example for Additional Constraints

The loop is executed for at most 20 times when k is initialized with a non-negative number:

$$x_3 \leq 20x_1.$$

The basic block for $j = 0; ok = true;$ is executed for at most one time:

$$x_6 \leq x_1.$$

WCET: ILP Formulation

$$\text{maximize } \sum_{i=1}^N c_i \cdot x_i$$

$$\text{such that } d_1 = 1$$

$$\sum_{j \in \text{in}(B_i)} d_j = \sum_{k \in \text{out}(B_i)} d_k = x_i, \quad \forall i = 1, \dots, N$$

additional linear constraints

Cache Analysis

Value Analysis: Motivation and Method

- Motivation
 - Provide access information to data-cache/pipeline analysis
 - Detect infeasible paths
 - Derive loop bounds
- Method
 - Calculate intervals at all program points
 - By considering addresses, register contents, local and global variables.

Abstract Interpretation

Perform the program's computation using value descriptions or abstract values in place of the concrete values.

Fully Associative Caches

Set-Associative Caches

Special cases:

- direct-mapped cache: only one line per cache set
- fully-associative cache: only one cache set

Replacement Policies

- Least-Recently-Used (LRU) used in
INTEL PENTIUM I and MIPS 24K/34K
- First-In First-Out (FIFO or Round-Robin) used in
MOTOROLA POWERPC 56X, INTEL XSCALE, ARM9,
ARM11
- Pseudo-LRU (PLRU) used in
INTEL PENTIUM II-IV and POWERPC 75X
- Most Recently Used (MRU) as described in literature

Each cache set is treated independently:

→ Set-associative caches are compositions of fully-associative caches.

Cache Analysis for LRU

Two types of cache analyses:

- ① Local guarantees: classification of individual accesses
 - Must-Analysis \longrightarrow Underapproximates cache contents
 - May-Analysis \longrightarrow Overapproximates cache contents
- ② Global guarantees: bounds on cache hits/misses

Challenges for Cache Analysis

Challenges for Cache Analysis

Using Abstract Interpretation

Collecting Semantics =
set of states at each program point that
any execution may encounter there

Two approximations:

Collecting Semantics uncomputable

\subseteq Cache Semantics computable

$\subseteq \gamma(\text{Abstract Cache Sem.})$ efficiently com-
putable

Least-Recently-Used (LRU): Concrete Behavior

“Cache Miss”:

“Cache Hit”:

LRU: Must-Analysis: Abstract Domain

- Used to predict *cache hits*.
- Maintains *upper bounds on ages* of memory blocks.
- Upper bound \leq associativity \rightarrow memory block definitely cached.

Example

... and its interpretation:

Abstract state:

{x}
{}
{s,t}
{}

age 0

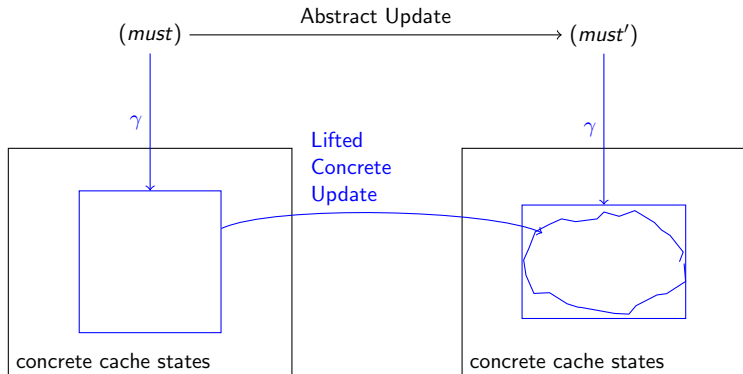

age 3

Describes the set of all concrete cache states in which x , s , and t occur,

- x with an age of 0,
- s and t with an age not older than 2.

$$\gamma(\left[\{x\}, \{\}, \{s, t\}, \{\}\right]) = \{[x, s, t, a], [x, t, s, a], [x, s, t, b], \dots\}$$

Sound Update – Local Consistency

LRU: Must-Analysis: Update

“Potential Cache Miss”:

“Definite Cache Hit”:

Why does not t age in the second case under Must-Cache analysis?

LRU: Must-Analysis: Join

Need to combine information where control-flow merges.

Join should be conservative:

- $\gamma(A) \subseteq \gamma(A \sqcup B)$
- $\gamma(B) \subseteq \gamma(A \sqcup B)$

“Intersection + Maximal Age”

LRU: Must-Analysis: Join

Need to combine information where control-flow merges.

Join should be conservative:

- $\gamma(A) \subseteq \gamma(A \sqcup B)$
- $\gamma(B) \subseteq \gamma(A \sqcup B)$

“Intersection + Maximal Age”

LRU: Must-Analysis: Join

Need to combine information where control-flow merges.

Join should be conservative:

Join should be conservative:

- $\gamma(A) \subseteq \gamma(A \sqcup B)$
- $\gamma(B) \subseteq \gamma(A \sqcup B)$

“Intersection + Maximal Age”

LRU: Must-Analysis: Join

Need to combine information where control-flow merges.

Join should be conservative:

- $\gamma(A) \subseteq \gamma(A \sqcup B)$
- $\gamma(B) \subseteq \gamma(A \sqcup B)$

“Intersection + Maximal Age”

How many memory blocks can be in the must-cache?

LRU: May-Analysis: Abstract Domain

- Used to predict *cache misses*.
- Maintains *lower bounds on ages* of memory blocks.
- Lower bound \geq associativity
→ memory block definitely *not* cached.

Abstract state:

$\{x, y\}$	age 0
$\{\}$	
$\{s, t\}$	
$\{u\}$	age 3

and its interpretation:

Describes a set of all concrete cache states, where no memory blocks except x , y , s , t , and u occur,

- x and y with an age of at least 0,
- s and t with an age of at least 2,
- u with an age of at least 3.

$$\gamma([\{x, y\}, \{\}, \{s, t\}, \{u\}]) = \{[x, y, s, t], [y, x, s, t], [x, y, s, u], \dots\}$$

LRU: May-Analysis: Update

“Definite Cache Miss”:

“Potential Cache Hit”:

Why does t age in the second case?

LRU: May-Analysis: Join

Need to combine information where control-flow merges.

Join should be conservative:
